Maestro Flow

Maestro's AI-native orchestration surface for APIs, AI agents & enterprise services

Meet the team!

Agenda

Introduction to Maestro Flow

Maestro Flow – Core Concepts

Advanced AI and Agentic Workflows

Live Demo

Q & A

What is UiPath Maestro Flow ?

An AI-native orchestration surface, built on the Maestro runtime. You build a Flow process by placing nodes on a canvas and connecting them - then debug, evaluate against real data, and deploy, all before it runs as a governed process in Orchestrator.

Canvas-Based	AI-Native	Maestro Runtime	Studio Web / VS Code
Build with nodes, not raw code	Built for agents & AI orchestration	Enterprise-grade reliability	Build here, deploy via Orchestrator

Flow processes run as agentic processes in Orchestrator - alongside RPA workflows, API workflows, and AI agents.

Its role in the ecosystem: Flow is one of several ways to build on UiPath. It's not a layer above RPA and AI agents - it runs as its own agentic process, right alongside them in Orchestrator. (If you've used Maestro BPMN before, Flow is a different product on the same runtime.)

Maestro Flow vs. Traditional Studio Development

API-first orchestration vs. UI-driven, single-workflow automation

Traditional Studio Development

- UI-first: automates screens, apps, and clicks
- Single workflow executes a bounded task end to end
- One robot runs the process, start to finish
- Best for: repetitive, well-defined desktop/web tasks

Maestro Flow

- API-first: nodes call REST endpoints, agents & services
- Built visually on a canvas - debug, evaluate, then deploy
- Runs as an agentic process alongside RPA & API workflows
- Best for: AI agent orchestration, approvals, integrations

They're complementary - both run as processes in Orchestrator; Flow is the tool of choice when the job is orchestration, not UI automation.

Where to Find Maestro Flow

Coordinating the Enterprise Automation Stack

UiPath Community

One process, five moving parts - Maestro Flow keeps them in sync

Flow sequences which node runs next, passes data between them, and gives you one place to debug, evaluate, and monitor the whole process.

Flow Building Blocks

The four categories that structure a Maestro Flow

TRIGGERS	ACTIONS	GATEWAYS	TASKS
Starts workflows HTTP Trigger Timer Trigger	HTTP Request Data Operation Robot Invocation AI Agent	Conditional Parallel Loop Error Catch	Human-in-the-loop Human Task via Action Center

Build flows by combining triggers, actions, gateways, and tasks.

Each building block has a defined role in the orchestration lifecycle.

Flow Lifecycle & Contract-Based Data Flow

Each node defines an input/output schema. Data moves through JSON contracts, creating type-safe connections that prevent runtime errors.

Contract-based data flow keeps every handoff explicit and type-safe.

Best Practices for Structured, Scalable Design

Design for modularity, reliability, and efficient execution

Design Principles

- Keep flows modular- one responsibility per subflow
- Use consistent naming for nodes and variables
- Implement error handling at every gateway
- Design for idempotency and safe re-execution

Performance Tips

- Minimize payload sizes between nodes
- Use parallel gateways for independent operations
- Cache frequently accessed external data
- Monitor execution metrics regularly

These practices support reliable, scalable orchestration.

Configuring AI Agent Nodes

Native AI provider support

Claude	OpenAI GPT	Google Gemini	Azure OpenAI
Anthropic Advanced reasoning & analysis	OpenAI Versatile language model	Google Multimodal capabilities	Microsoft Azure-hosted OpenAI deployment

Choose the provider that best supports the workflow's reasoning, language, or integration needs.

All providers are configured through native AI Agent nodes.

AI Agent Node Settings

Configure the provider, model behavior, context, and response contract.

Key settings

- Model selection - choose a provider-specific model variant
- Temperature control - adjust creativity (0.0–1.0)
- Prompts - define AI behavior using system and user prompts
- Context window - set the token limit

Configuration intent

Configuration summary

Output schema definition - structure the response format.

Guardrails - built-in safety and quality checks for agent behavior

Common Agentic Patterns

Reusable patterns for agentic workflow design

ROUTER Pattern

- Intent classification
- Directs input to a specialized AI handler based on intent.
- Use case: customer inquiry routing by issue type.

GENERATOR Pattern

- Content creation
- Creates content, summaries, or responses using LLM capabilities.
- Use case: auto-generating email responses from ticket data and customer history.

EXTRACTOR Pattern

- Data extraction
- Pulls structured data from unstructured documents into validated JSON.
- Use case: invoice extraction from PDFs into database records.

CRITIC Pattern

- Quality validation
- Validates and scores AI output against quality criteria.
- Use case: reviewing generated code before production deployment.

Patterns can be combined in sequence for complex workflows — e.g., Extract → Generate → Critic.
